Up to now, more than 4000 people have been treated with gene therapy in the context of clinical studies, mostly for AIDS or cancer. The method is always similar or identical: The healing gene is brought to the desired cells using a "gene taxi" (scientifically, a gene vector), for instance to a tumour cells. The greatest problem in gene therapy is the transport, i.e. how to route the healing gene to the desired cells most efficiently.

Experimental cancer treatments are non-medical therapies intended to treat cancer by improving on, supplementing or replacing conventional methods (surgery, chemotherapy, radiation, and immunotherapy). Experimental cancer treatments cannot make medical claims. The term experimental cancer treatment could thus be substituted for "non FDA approved cancer treatment."
